Rencontres au sommet, March 26, 2024

< 日 > < 同 > < 三 > < 三 >

This project has received funding from The European Unions's Horizon 2020 Research and innovation programme Under grant agreement No 840383. Abscission: the process shedding of various parts of an organism, such as a plant dropping a leaf, fruit, flower, or seed.

An optimal execution of the abscission process is of major importance for species survival

Environmental variations impact abscission process with varying effects over developmental stages

Question:

Identify the most relevant set of environmental factors and the time periods at which they modulate the abscission process

(4月) トイヨト イヨト

# Oil palm: fruit abscission process

The fruit abscission of oil palm trees (Dataset provided by "le Centre de Recherches Agricoles-Plantes Pérennes (CRA-PP)" (Tisné et al., 2020))

Priors

# Oil palm: fruit abscission process

To identify the environmental variables and the time periods affecting the oil palm fruit abscission process

#### Statistical model

$$y = \mu + \sum_{g=1}^{G} X_{g} \beta_{g} + \varepsilon, \ \varepsilon \sim \mathcal{N}_{n}(0, \sigma^{2} I_{n})$$

with

- $\mathbf{y} = (y_1, \dots, y_n)'$  the *n*-vector of outcomes,
- X<sub>g</sub> = [x'<sub>g1</sub>,...,x'<sub>gT</sub>] a n × T matrix of covariates measured at T regular spaced times for g = 1,..., G,
- $\beta_g = (\beta_{g1}, \dots, \beta_{gT})'$  the *T*-vector of coefficients associated to group *g*,
- $\boldsymbol{\varepsilon} = (\varepsilon_1, \dots, \varepsilon_n)'$  the *n*-vector of residuals,
- $\sigma^2$  the residual variance.

#### Statistical model

$$y = \mu + \sum_{g=1}^{G} X_{g} \beta_{g} + \varepsilon, \ \varepsilon \sim \mathcal{N}_{n}(0, \sigma^{2} I_{n})$$

#### Objectives

- To identify environmental variables → Selection of groups of temporally correlated variables (or time series)
- $\bullet\,$  To identify time periods  $\rightarrow\,$  Selection of correlated variables within groups
- → Need to develop statistical approaches **selecting** groups of correlated variables and variables within groups while considering the group **structure** and the natural order of variables within groups

#### Statistical challenges

- $\bullet\,$  High correlation between consecutive variables  $\rightarrow\,$  ill-conditioned and over-fitting problems
- Double selection
- $\rightarrow\,$  Bayesian framework: selection and integration of dependence structure between variables taken into account by specifying specific priors

#### Selection

To shrink towards zero small coefficients while leaving large signals large: **Shrinkage** priors

#### Structure

Priors with a **variance-covariance matrix** related to structure information between variables

#### In fruit abscission process context

Continuous shrinkage priors (Park and Casella, 2008; Polson and Scott, 2011) with a specific covariance structure to identify the environmental variables and the time periods affecting the oil palm fruit abscission process

Usual approach to take into account time structure within covariate matrix while imposing sparsity on coefficients

Global-local parametrization

$$\prod_{t=1}^{T} \frac{1}{\sqrt{2\pi \upsilon^2 \gamma_t^2 \sigma^2}} \exp\left(-\frac{\beta_t^2}{2\upsilon^2 \gamma_t^2 \sigma^2}\right) \quad \text{and} \quad \prod_{t=2}^{T} \frac{1}{\sqrt{2\pi \lambda^2 \omega_t^2 \sigma^2}} \exp\left(-\frac{(\beta_t - \beta_{t-1})^2}{2\lambda^2 \omega_t^2 \sigma^2}\right)$$

 Global shrinkage parameters ν and λ: perform shrinkage on all coefficients and their differences

• Local shrinkage parameters  $\gamma_t$  and  $\omega_t$ : allow true large signals to escape from the overall shrinkage

#### Bayesian fused priors

# To investigate the trade-off between strong shrinkage prior on coefficients and their differences

#### Figure: Continuous shrinkage prior distributions

#### Inference: technical aspects

Conjugate prior distributions:

$$eta_g|\gamma_g, \lambda^2, oldsymbol{\omega}_g, \sigma^2 \sim \mathcal{N}_T(0, \sigma^2 oldsymbol{Q}_g^{-1}), \ \ g = 1, \dots, G$$

where  $Q_g$  is equal to

$$oldsymbol{Q}_g = igg( oldsymbol{\Upsilon}_g^{-1} + oldsymbol{D}_g^{ op} oldsymbol{\Omega}_g^{-1} oldsymbol{D}_g / \lambda^2 igg).$$

For all shrinkage parameters (Makalic and Schmidt, 2015):

$$x \sim \mathcal{C}^+(0,1) \hspace{0.2cm} \Leftrightarrow \hspace{0.2cm} x^2 | \xi \sim IG(1/2,1/\xi), \hspace{0.2cm} \xi \sim IG(1/2,1),$$

All full conditional distributions have closed forms  $\rightarrow$  Gibbs sampler (GitHub: https://github.com/Heuclin/GroupFusedHorseshoe)

#### Simulation study

Simulation design:

- p = 1500 covariates divided into G = 1, 10, 30, 100 groups
- $T = \min\left(\frac{p}{\max(10,G)}, 60\right)$
- n = 150 and  $\sigma^2 = 1, 4$

#### Simulation results

Priors	МСС	MSE <sub>z</sub>	MSE <sub>nz</sub>
Diff_Coeff			
HS_NhC	0.90688	0.00003	0.01485
HS₋NE	0.90018	0.00067	0.05000
HS₋HS	0.06456	0.00000	2.33525
NE_NE	0.21203	0.00273	0.04602

Table: Matthews Correlation Coefficient (*MCC*), mean squared errors of true zeroes (*MSE<sub>z</sub>*), and mean squared errors of non-zero coefficients  $MSE_{nz}$  using the different priors with residual variance  $\sigma^2$  equal to 1 and G = 1.

# Simulation results

Figure: (a) Mean squared errors of true zero coefficients  $MSE_z$ , (b) Mean squared errors of non-zeroes ( $MSE_{nz}$ ), and (c) Matthews Correlation Coefficient (MCC) using the different priors with residual variance  $\sigma^2$  equal to 1, and G = 5, 10, 30, 100.

# Application on oil palm

#### Data

- 1,173 bunches (statistical unit)
- Outcome (y): number of days from pollination to fruit drop
- 5 climatic variables: Tmax, Tmin, Relative air humidity (RH), Rainfall (R), Solar radiation (SR)
- 5 ecophysiological variables: Maximum daily vapor pressure deficit (VPD), Fraction of transpirable soil water (FTSW), Supply-demand ratio (SD), Daily reproductive demand (DRD)
- 121 time points for each environmental variables: p = 1,210 predictors greater than n = 1,173 observations

# Application on oil palm

Figure: Estimated coefficient profiles for DRD, SD, SR, Tmin. Gray shadows represent the 95% credible interval.

- Identification of 4 environmental variables: DRD, SD, SR, Tmin
- Identification of relevant time periods
  - Tmin: smooth effect during the inflorescence development
  - DRD and SD: punctual effects at the end of the fruit bunch development
  - SR: smooth effect at the end of the fruit bunch development

F. Mortier

# **Conclusion/Perspectives**

#### Conclusion

Four Bayesian priors proposed:

- Able to handle different structures and to select relevant variables and/or groups of variables,
- Easily adaptable to a broad type of dependence structures : applicable in various applications (varying coefficient models, near infrared spectroscopy context (NIRS), QTL mapping, ...)

#### Perspectives

- To integrate prior knowledge on strengths of connections,
- To integrate dependence structures between observations,
- To extend to multivariate case (Y multivariate),
- To consider a multi-dimensional indexation.
